**Liquid-phase equilibria in three-component systems.** R. V. Mertulin and V. V. Parkacheva (*J. gen. Chem. USSR.*, 1930, 29, 1929--1936 [U.S. transl., 1997--2004]) --A general discussion of typical equilibrium diagrams indicates that, in multi-component systems, each binary layer has its own independent region of layer formation and that displacement of one such region by another may occur with change in temp. These conclusions are confirmed by observed data for the system  $H_2O-Et_2O-(CH_3)_2CN$ , which contains an independent region of layer formation linked with layer formation in the binary system  $H_2O-(CH_3)_2CN$ , and displaced with falling temp. by the corresponding region extending from the equilibrium area of the three liquid phases. W. J. BAKER.

Solvent systems. R. V. Mertalin and V. D. Vasev (Molotov State Univ.). *Zhur. Obshchei Khim.* 21, 417-20 (1951); *J. Gen. Chem. U.S.S.R.* 21, 463-74 (1951) (English trans.).—The investigation was made to det. the effect of a 3rd component in increasing the soly. of a solid substance in a given solvent. Specifically, the soly. of solid succinonitrile was detd. in EtOH in the presence of Et<sub>2</sub>O. The system succinonitrile-EtOH was first studied. Two immiscible liquids are formed over a concn. range from 21.2 to 87.0% EtOH with a eutectic temp. ("monotectic") of 11.5°. At lower EtOH concns. the m.p. rises to 30° for pure succinonitrile; and at higher concns. it decreases, presumably finally encountering another eutectic, but crystn. temps. were not investigated below +6°.

The ternary system succinonitrile-EtOH-Et<sub>2</sub>O was studied, and isotherms for the ternary system were calcd. at 10, 12, 15, and 20°. At 10° the 1-phase region is a band extending along the EtOH-Et<sub>2</sub>O side of the triangle, starting at 88% EtOH on the EtOH-succinonitrile side, rising to a slight max. at a point with the compn. 36.1% EtOH, 42.3% Et<sub>2</sub>O, and then tapering off to a point on the Et<sub>2</sub>O-succinonitrile side contg. 96% Et<sub>2</sub>O. All the points on the liquidus curve at 10° are connected by tie-lines with the succinonitrile corner, there being no sepa. into immiscible liquids below 11.5°, the eutectic temp. At 12° the diagram is similar, except that there appears a small, roughly cigar-shaped, 2-liquid-phase region, with 1 end on the EtOH-succinonitrile side at 20-22% EtOH, the other end at approx. 18% Et<sub>2</sub>O, 10% EtOH. At 15° the 2-liquid-phase region is larger, and the 1-liquid-phase region is also larger and the max. is more pronounced. At 20° the 2-liquid-phase region is considerably larger, as is the 1-liquid-phase region, and they are elongated towards each other so that they are almost in contact. The increase in soly. of succinonitrile is attributed to tact. The increase between EtOH and Et<sub>2</sub>O, which is a general requirement where the addn. of a 3rd component increases the soly. in this way. Arild J. Miller

 siya dvukh zhidkikh faz v sisteme n.-geksan-nitrobenzol-anilin)

PERIODICAL: Zhurnal obshchey khimii, 1952, Vol 29, Nr 2,  
 pp 345 - 350 (USSR)

ABSTRACT: The problems of practical importance concerning the extraction  
 of substances from solutions, the decomposition by layers of  
 the solutions of two mutually soluble liquids by salting out,  
 the drying of solutions, etc. are connected with the problem  
 of distributing the third substance among mutually insoluble  
 or weakly soluble liquids. Berret's distribution law does  
 not take into the possibility of a variation in the reci-  
 procal ratio of the components with the simultaneous varia-  
 tion of the third component content in the mixtures. In-  
 far as the problem concerning the distribution of the third  
 component among two phases being in equilibrium considers the  
 equilibrium of two liquid phases of systems consisting of  
 three components the relationship occurring in this connection

Card 1/3

Investigation of the Equilibrium of Two Liquid Phases  
in the System n-Hexane-Nitrobenzene-Aniline

8.7/73-23-2-1/71

help to approach the solution of the problem. Mertsin, R. V. (Ref 3) determined certain rules governing the distribution of nodes (lines linking the compositions of the conjugated solutions in the diagram triangle) in the range of the two-phase liquid equilibrium in the system consisting of three components. He showed that the character of the binodal curve and the distribution of the above-mentioned nodes within the decomposition by layers are interrelated. The purpose of the present paper was the experimental confirmation of the rules governing the distribution of the above-mentioned nodes in the system n-hexane-aniline-nitrobenzene. The system was investigated with respect to solubility at 10 and 20°. It is shown that the critical point follows the system hexane - aniline - nitrobenzene. Based on Mertsin's method and further investigations a system of nodes was plotted within the decomposition by layers and the rule laid down by him was thus confirmed. There are 3 figures, 4 tables and 4 Soviet references.

TITLE: Investigation of the Equilibrium of Three Liquid Phases in the  
Four-component System Water-n.-Hexane-Aniline-Nitrobenzene  
(Issledovaniye ravnovesiya trekh zhidkikh faz v chetyrekhkom-  
ponentnoy sisteme voda-n.-geksan-anilin-nitrobenzol)

PERIODICAL: Zhurnal obshchey khimii. 1959, Vol 29, Nr 2, pp 350-357 (USSR)

ABSTRACT: In investigating the equilibrium of two liquid phases in the  
system hexane-aniline-nitrobenzene the authors had shown the  
regularity in the distribution of the nodes, determined by the  
interaction of the components in the predominant double system  
(Ref 1). The present paper is the further development of the  
"predominance theory", which is considered in a complicated  
case, i.e. the case of the four-component system water-n.-  
hexane-aniline-nitrobenzene. As is shown by the investigations  
illustrated in the figures, ternary and binary systems may be  
predominant in systems of such a type. In dependence on this  
circumstance the content formation of the three liquid phases,  
as well as its development may vary. The purpose of the present  
paper was the experimental confirmation of the rule governing

Card 1/2

the directional arrangement of the nodal diagram triangles of the three liquid phases in the system water-n -hexane-aniline-nitrobenzene, as is done in detail in the experimental part. All horizontal sections offer the same picture concerning the range of the three existing liquid phases. The nodal triangles are in the same direction, parallel to the right of the secant, which is drawn to the nitrobenzene-aniline. It was shown that the sectional method can be used to investigate the equilibrium of the three liquid phases in four-component systems. The rule concerning the directional arrangement of nodes was found to be valid also in the case of four-component systems. There are 11 figures, 4 tables, and 3 Soviet references.

TITLE: On the Methods and Laws of the Establishment of Equilibrium of the Four Liquid Phases in Condensed Quaternary Systems

PERIODICAL: Zhurnal obshchey khimii, 1959, Vol 29, Nr 8, pp 2474 - 2480 (USSR)

ABSTRACT: In contrast to some papers on the equilibrium of two- and three-phase liquid physical states, no systematic investigations of the equilibrium of the liquid phases in the above systems have hitherto been published. The systematic solution of the problems raised by the equilibrium of the number of liquid phases within systems of a different number of components, is, however, only possible by determination of the mode of formation of the maximum number of liquid phases within a system of given number of components and by determination of its laws of formation. The authors attempted to explain the manner in which the state of the four liquid phases appears in the quaternary system. The mode of formation of the four phases within the quaternary system is assumed to be connected with the mode of formation of the three liquid phases within the ternary system. It was shown that the temperature at the beginning of formation

Card 1/2

Equilibrium of the Four Liquid Phases in Condensed  
Quaternary Systems

SOV/79-29-8-4/81

of the four-phase state within the quaternary system must be higher than the temperatures at the beginning of formation of the three-phase state within two ternary systems enclosing the predominant binary system, and that in some cases it must exceed the temperatures at the beginning of formation of the three-phase state within the three enclosing three-phase systems. Near the temperatures at which the four-phase state is attained, two faces of the tetrahedron of the four-phase state must have the same direction, which corresponds to the law of direction of the triangles of the three liquid phases within the quaternary system with a predominant binary system (Figures). There are 9 figures and 2 Soviet references.

TITLE: Concerning the Distribution Law of the Lines in the Three-Phase State of a Four-Phase System

PERIODICAL: Zhurnal obshchey fiziki, 1960, Vol. 31, No. 1, p. 100-103, USSR.

ABSTRACT: A triangular diagram, whose vertices correspond to the different components of a four-phase system, is constructed. It illustrates a ternary composition diagram. A four-component system can be similarly represented in four equilateral triangles that form a tetrahedron. Let vector  $\vec{r}$  represent the composition of a mixture. Any point  $\vec{r}$  in the composition tetrahedron AB<sub>1</sub>CD of Fig. 1 represents a three-phase state. The state of the different regions of two-phase diagrams is also indicated. Then, any section  $\vec{r}$  parallel to the base of the tetrahedron and a section that contains every DC and AB edge AB representing the only completely stable mixture in the system, will have those sections of the region of three-phase state. In the former section only two phases

Card 1/4

in the Three-Phase State of Four-Terminal  
Systems

30"

lines, in the latter by three (Fig. 1, 2). Since the distribution of tie-lines in interlink sections of the system is a function of mutual relationships of the components, the completely miscible pair AB receives the greatest amount among the total of six pairs. This can be realized from the fact that in the  $1/2$  and  $1/3$  sections the total of two- and three-phase interlink sections of the system are best with respect to the mutual relationship of A and B components. Phase III, which consists of ear and

TITLE: Effect of brucellosis antigens on splenic cell cultures of sensitized guinea pigs

SOURCE: Byulleten' eksperimental'noy biologii i meditsiny, v. 59, no. 3, 1965, 68-71

TOPIC TAGS: guinea pig, brucellosis, antigen, spleen, culture method, E. coli, brucella, gamma globulin

ABSTRACT: The effect of brucellosis antigens on splenic cells was investigated in tissue cultures of guinea pigs sensitized with brucella, E. coli, and human gamma globulin. Animals were decapitated at the height of sensitization and spleens were extracted. Splenic cells were prepared for culturing in a test tube containing mica. At the time the splenic cells ( $5 \times 10^6$ /ml) were placed into the test tube they were subjected to the action of a brucella culture killed by heating, and were subjected again after 48 hrs when the culture

Card 1/3

L 44203-65

ACCESSION NR: AP5009193

medium was changed. Mica slides were stained 24, 48, 72, and 96 hrs after culturing for histological investigation. Cells found on test tube walls were separated with trypsin and measured with a hemocytometer. The cytotoxin index was based on the average number of cells with antigen found in test tubes divided by the average number of cells in control test tubes. Microscopic examinations determined the percentage of damaged cells per 1,000 count in the various fields of vision. Brucellosis antigen action produced a marked cytotoxic effect on splenic cells sensitized with brucella characterized by a decrease in absolute cell count, macrophage damage, and reduced percentage level of lymphoid cells. The brucellosis antigens did not produce any marked cytotoxic effect on the splenic cells of healthy animals or of animals sensitized with *E. coli* or human gamma globulin. The cytotoxin action mechanism appears to be specific and related to interaction of the antigens with the antibodies present in the sensitized cells. Orig. art. Has: 2 figures.

TITLE: High-rigidity dynamometer for measurement of rapidly changing forces *gm*

SOURCE: Leningrad. Politeknicheskii institut. Trudy, no. 250, 1965, 100-103

TOPIC TAGS: piezoelectric transducer, lathe, oscillograph, voltmeter, metal turning

ABSTRACT: For measurement of the forces involved in multiple blade lathe turning of metal parts, a dynamometer of high rigidity is required, since a relatively flexible mounting (as is required for generation of measurement current in all currently known designs) of any blade would essentially change the operating conditions of the lathe. With multiple blades, the mounting must also be very small. The piezoelectric transducers now used satisfy the requirements for rigidity, but do not transmit all the cutting forces for measurement. In order to satisfy this requirement, two-sided mounting of piezoelectric transducers was used, with the two oppositely mounted transducer elements connected with reversed electrical polarity. A vacuum tube voltmeter connected with an oscillograph for permanent readout completed the apparatus. Orig. art. has: 3 figures and 1 formula. /JPRS/

✓ Mertvecova, M. A. Analogue of the process of tangent hyperbolas for general functional equations. Doklady Akad. Nauk SSSR (N.S.) 88, 611-614 (1953). (Russian) The process of the title is a cubically converging iteration for solving an equation  $f(x)=0$  in the complex field, as discussed by Salchov [same Doklady (N.S.) 82, 525-528 (1952); these Rev. 14, 91]. Following the work of Kantorovich and others for Newton's method, the author extends the process to solve (\*)  $P(x)=0$ , where  $P$  carries a normed space  $X$  into a like space  $Y$ , and has a third Fréchet differential. The formula is  $x_{n+1}=x_n-Q_n\Gamma_n P(x_n)$ , where  $\Gamma_n=[P'(x_n)]^{-1}$  and  $Q_n=[I-2^{-1}\Gamma_n P''(x_n)\Gamma_n P(x_n)]^{-1}$ . In two theorems the author gives conditions for (\*) to have a unique solution  $x^*$  in a region of  $X$ , and estimates the size of  $\|x_n-x^*\|$ , which vanishes like  $2^{-nC^*}$ ,  $0<C^*<1$ . The process is applied to a class of nonlinear integral equations, and one numerical example is cited. G. E. Forsythe.

TITLE: Kinetics of the radiochemical graft copolymerization of acrylonitrile with capron fiber

SOURCE: Ukrainskiy khimicheskiy zhurnal, v. 30, no. 12, 1964, 1319-1321

TOPIC TAGS: vapor seeding copolymerization, capron fiber, acrylonitrile vapor, copolymerization constant, radiation polymerization, graft copolymer, polyacrylonitrile

ABSTRACT: Degreased, drawn, capron fiber was irradiated (Co<sup>60</sup> source, 1600 curies, 100 rad/sec, 10<sup>-3</sup> mm Hg, room temperature, 0.25 Mrad) and exposed to an acrylonitrile vapor at 80 mm pressure in a study of the kinetics of vapor seeding graft copolymerization which does not involve formation of a homopolymer. Graphs illustrate the effects of temperature (22-60C, 0-24 hrs), radiation dosage (0-20 Mrad) and monomer vapor pressure (30-80 mm Hg, 0-10 hrs). The authors calculated constants for the rate of chain growth, rate of chain disruption, the apparent activation energy (1.9 Kcal/mol), activation energy of chain growth and chain disruption, the average distance between initiation centers (120 A) and the average lengths of chains. An increase in monomer

Card 1/2

L 25238-65

ACCESSION NR: AP5002750

vapor pressure led to an increase in the quantity of copolymerized polyacrylonitrile. An increase in temperature decreased the amount of copolymerization, while an increase in radiation dosage above 2 Mrad had little effect. "The authors are indebted to A. Ya. Rozovskiy for participating in the evaluation of the results". Orig. art. has: 4 figures and 1 formula.

SOURCE: AN UkrSSR. Modifikatsiya svoystv polimerov i polimernykh materialov (Modification of the properties of polymers and polymeric materials). Kiev, Naukova dumka, 1965, 15-17.

TOPIC TAGS: nylon, caprone fiber, acrylonitrile, graft copolymer

ABSTRACT: A study has been made of the strength of capron-fiber-acrylonitrile graft copolymers prepared by radiation-induced gas-phase graft-copolymerization. Acrylonitrile in the gaseous state was grafted to capron cord no 34.5 which had been preirradiated with  $\gamma$ -rays from a  $\text{Co}^{60}$  source. Dose rate was 100 rad/sec. The effect of the number and length of grafted chains on the strength of the copolymer was studied. The number of grafted chains was varied by controlling the irradiation dose. The grafted chain length was modified by controlling the reaction time. The results of tensile tests showed that: 1) irradiation of the original fiber lowers its tensile strength by increasing the number of surface defects, and 2) the

Cord 1/2

2

L 14492-66

ACC NR: AT6006237

strength of the modified fiber is determined solely by the total amount of the grafted layer and does not depend on the number and length of the grafted chains. The highest strength was exhibited by fibers containing 4 to 5% polyacrylonitrile. The study resulted in the conclusion that strengthening of the fiber is the result of a "healing" of its surface defects by small amounts of polyacrylonitrile. Orig. art. has: 2 figures and 1 table. TITLE: Production of isoprene from dimethyldioxan. I. The  
role of catalyst and support

PERIODICAL: Zhurnal obshchey khimii, v. 32, no. 12, 1962,  
3987-3990

TEXT: In connection with work carried out at the authors' Institute in Bucharest on the production of isoprene from isobutylene and formaldehyde via 4,4-dimethyl-1,3-dioxan (DMD), the effect of the composition of the catalyst for the vapor-phase conversion of DMD to isoprene on its selectivity, isomerizing effect, etc. has been studied. Standard conditions found to be optimal in preliminary experiments were used, namely: 270°C and a space velocity of feed of DMD of 0.4 hr<sup>-1</sup>. The highest activity was possessed by a catalyst consisting of acid calcium phosphate on a silica/5% alumina support, the nature of the support being important. With this cata- ✓

D424/D307

lyst, the selectivity fell as the temperature was increased from 150 to 350°C but the maximum total conversion (~65%) was obtained at ~300°C, the selectivity then being of the order of 85%. By-products found (by gas chromatography) included isobutylene, 2-methylbut-2-ene, methyltetrahydropyran, 2-methylbutan-1-ol, isovaleraldehyde, and dimers and trimers of isoprene. The fact that the support alone had a small catalytic activity due to its Lewis acid sites and leading mainly to isobutylene is considered to show that the activity of the calcium phosphate catalyst depends on the presence of Brønsted acid sites. The catalyst is not appreciably affected by the usual impurities in DMD but is poisoned by sulfur (mercaptans). It can also be used for the production of other dienes, e.g. 2-phenylbutadiene, by analogous reactions. There are 5 figures.

TITLE: Production of isoprene from dimethyldioxan. III.  
Acidity and activity of the cracking catalyst

PERIODICAL: Zhurnal obshchey khimii, v. 32, no. 12, 1962,  
3992-3997

TEXT: The present article deals with the production of  
isoprene by the vapor-phase catalytic cracking of dimethyldioxan  
and shows that the activity of the catalyst depends on the presence  
of Brønsted acid sites, the reaction being analogous to that carried  
out in solution with acid catalysts. The catalysts used in the pre-  
sent work were prepared by calcining silica + 5% of alumina at 500°C,  
impregnating this support with solutions of phosphates (sodium, am-  
monium, calcium, etc.) of various concentrations, and calcining at  
400°C. The proton acidity of the catalysts was measured by ion-ex-

Card 1/3

Production of isoprene ....

3/079/62/032/012/006/003  
D424/D307

change with neutral ammonium acetate solution, and their surface area by a simplified B.T. method. Plotting the increase in activity (total conversion under standard conditions) of the catalyst against increase in proton acidity gives a characteristic curve consisting of two rectilinear sections, the slope suddenly becoming more pronounced at a content of active phase in the catalyst of about 4%, corresponding to an acidity of 0.050 m-equiv/g. The selectivity also rises very rapidly and linearly, up to a proton acidity of about 0.10 m-equiv/g, after which it continues to rise very slowly, the conversion of dimethyldioxan to isoprene, however, remaining constant (because of a slight decrease in the total conversion) at about 47% under standard conditions (after 3 hrs with a space velocity of 0.4 hr<sup>-1</sup>, at 300°C). The relationship between the first-order velocity constant and the acidity of the catalyst is similar to that for homogeneous acid catalysis. The specific surface of the catalyst falls as the content of active phase is increased from 0 to 34%, except that at 2% it is greater than at 5%. During working, as the catalyst becomes coated with 'coke' its acidity diminishes and the conversion falls, the selectivity increasing slightly.

Card 2/3

Production of isoprene ...

S/079/62/032/012/006/008  
D424/D307

The nature of the curve of the increase in acidity with the amount of active phase is explained by the formation of aggregation polymers by the phosphate on the surface of the support. The dependence of the activity on the proton acidity is explained by the formation of active surface compounds by the dimethyldioxan at the Brønsted acid sites. The levelling off of the conversion to isoprene at a certain acidity is due to the decreased specific surface and consequent decreased adsorption. The main side reaction - the production of isobutylene - takes place at both Brønsted and Lewis acid sites and is therefore independent of the presence of the active phase. Because the Brønsted acid sites are screened to some extent from 'coking up' by their adsorption of the dimethyldioxan, the Lewis acid sites are lost more rapidly during the working of the catalyst, which accounts for the increase in selectivity during working. There are 6 figures and 2 tables. ✓

AUTHORS: Mervart, Z., Křen, J., and Loučka, P  
TITLE: Economic Analysis of the Effect of the Properties of  
Solvents on the Separation of 1,3-Butadiene by  
Extraction Rectification

PERIODICAL: Chemický průmysl, 1960, Nr 3, pp 132-135

ABSTRACT: The separation of the  $C_4$  hydrocarbon fraction, which is important in the manufacture of butadiene rubber, can be carried out by extraction rectification, using polar liquids which are selective for hydrocarbons with lower degree of saturation. Furfural, containing 4% of water (aqueous furfural), has been used by various authors for separating 1,3-butadiene (Refs 1 to 4). The authors investigated the possibility of using as solvent a mixture of acetone, containing 18% of water (aqueous acetone) and bis (2-chloroethyl) ether ("chlorex") (Ref 5). Flow sheets for both methods are given (Figs 1 and 2). The effect of the solvents on the relative volatility of the hydrocarbons, on the solubility of the hydrocarbons in the solvents, and on their properties under industrial conditions were compared (Table 1). The decisive economical factors were found to be the

corrosive and thermal properties of the solvents and the solubility of liquid hydrocarbons. Cost estimates for machinery when using aqueous acetone, aqueous furfural and chlorex are compared in Tables 2 and 3. Data on power consumption per ton of butadiene are compared in Table 4. The authors conclude that aqueous acetone is most satisfactory from an economical point of view, in spite of the fact that its use involves a more complicated technological process. There are 2 figures, 7 tables and 9 references, 2 of which are Czech, 6 English and 1 Soviet.

Title : Extraction of Uranium from Ores.

Orig Pub : Khimiya yadernogo goruyet-go [The Chemistry of Nuclear Fuels] (Dokl. in. uchenykh na Mezhdunar. konferentsii po miromu ispol'zovaniyu atom. energii, Zhenava, 1955) [Reports presented by foreign scientists at the International Conference on the Peaceful Applications of Atomic Energy, Geneva, 1955], Goskhimizdat, Moscow, 1956, 91-101.

Abstract : A survey. The primary ores are decomposed with concentrated acids; the secondary ores are treated with alkali (including  $\text{Na}_2\text{CO}_3$ ,  $\text{NaHCO}_3$ ,  $(\text{NH}_4)_2\text{CO}_3$ ). The choice of

of disintegration method depends on the composition of the ore. An increase in the contact time, temperature (20-90°) and in the grain size (from 10-20 mesh) in the acid-leach process leads to a gradual increase in the percent extraction of U. The addition of oxidizing substances increases the yield of U; the utilization of MnO<sub>2</sub> in amounts of 5 kg per ton of ore has proven most economical. The effect of the above-enumerated factors is the same in the alkali-leach method. The precipitation and filtration of muddy residues causes some difficulty in the treatment of the ores. New chemical flocculation agents have been developed to improve the settling of the cake after leaching. The separation of U from the cake and from the solutions is carried out by one of the following methods: chemical precipitation, used in the treatment of ores which give easily filterable solutions (mainly by

precipitation with alkali from bicarbonate solutions); fixedbed ion exchange (for the extraction of U from clarified sulfuric acid solutions); moving-bed ion exchange; and organic extraction (extraction of U from phosphoric acid solutions).
